We reanalyze our previous studies of neutrino-induced one-pion production on nucleons for outgoing πN invariant masses below 1.4 GeV. Our motivation is to get a better description of the $\nu_\mu n \rightarrow \mu^- n \pi^+$ cross section, for which current theoretical models give values significantly below data. We first notice that the largest contribution of the crossed Δ mechanism occurs precisely in this channel, being it a factor of three larger there than for $\nu_\mu p \rightarrow \mu^- p \pi^+$. Hence we ought to admit that the $n\pi^+$ amplitude receives sizable contributions from the spin 1/2 components included in the Rarita-Schwinger covariant Δ propagator, which are however suppressed when the Δ is nearly on-shell (direct Δ mechanism). We show how these spin 1/2 components are non-propagating and produce contact interactions. In this context, we point out that this discrepancy with experiment might be corrected by the addition of appropriate extra contact terms and argue that this procedure will provide a natural solution to the $\nu_\mu p \rightarrow \mu^- p \pi^+$ puzzle, since contact terms appear naturally within effective field theories, and in particular in chiral perturbation theory, as counter-terms with unknown strengths. To keep our model simple, in this work we propose to add just one new low energy constant. It changes the spin 1/2 components in the covariant Δ propagator and gives rise to two new contact terms. We use the $\nu_\mu n \rightarrow \mu^- n \pi^+$ cross section data to constraint the value of this additional constant. With this modification, we now find a much better description of the $\nu_\mu n \rightarrow \mu^- n \pi^+$ cross section, without affecting the good results previously obtained for other channels. We find that the new contact terms drastically suppress the contribution of the crossed Δ mechanism. Besides, we determine a value for the dominant axial nucleon to Δ form-factor at $q^2 = 0$ ($C_5^A(0)$) in remarkable agreement with that deduced from off-diagonal Goldberger-Treiman relation, and find that the Olsson's phases required to restore unitarity are now significantly smaller than in previous studies. Finally, we also explore how this change in the Δ propagator affects our predictions for pion photo-production and find also a better agreement with experiment than with the previous model.

I. INTRODUCTION

In Ref. [1] we developed a model for neutrino-induced one-pion production off the nucleon at low energies where, besides the dominant Δ mechanism (weak excitation of the $\Delta(1232)$ followed by its strong decay into $N\pi$), we included also non-resonant contributions required by chiral symmetry. These chiral background terms were evaluated using a nonlinear SU(2) chiral Lagrangian and we supplemented them with well known phenomenological form factors introduced in a way that respected both CVC and PCAC (conservation and partial conservation of the vector and axial currents, respectively). As for the dominant Δ contribution, the weak $N \rightarrow \Delta$ transition matrix element can be parametrized in terms of four vector C_{3-6}^V form factors and four axial C_{3-6}^A ones. C_6^V is exactly zero from CVC, while the rest of the vector form factors were determined from pion electroproduction and for them we adopted the values in Ref. [2]. Axial form factors are mostly unknown. In fact, one uses the weak pion production process as a tool to extract information on the axial nucleon to resonance transition form factors. The term proportional to C_5^A is the dominant one. Assuming the pion pole dominance of the pseudoscalar C_6^A form factor, PCAC gives its value in terms of C_5^A as $C_6^A = C_5^A \frac{M^2}{m_\pi^2 - q^2}$, where q^μ is the lepton transfer four momentum and M (m_π) the nucleon (pion) mass. We further adopted Adler's model [3] in which one has $C_3^A = 0$, $C_4^A = -\frac{1}{4}C_5^A$. We fitted C_5^A to data assuming a modified dipole parametrization. The experimental dataset consisted of the flux-averaged q^2 -differential $\nu_\mu p \rightarrow \mu^- p \pi^+$ cross section measured at Argonne National Laboratory (ANL) [4], which incorporated a kinematical cut $W_{\pi N} < 1.4$ GeV on the invariant mass of the final nucleon-pion pair. This was appropriate since our model ignored the contribution from higher mass resonances. From the fit we obtained $C_5^A(0) = 0.87 \pm 0.08$. This result was at variance with the value derived from the off-diagonal Goldberger-Treiman relation (GTR) that predicts $C_5^A(0) \sim 1.15 - 1.20$.

The disagreement with the GTR value got reduced in Ref. [5] where, following the work of Ref. [6], we included in our fit total cross sections measured at Brookhaven National Laboratory (BNL) [7] and we fully evaluated deuteron effects, the latter relevant since ANL and BNL data were actually obtained using a deuterium target. We had already noticed in Ref. [1] that the correct description of BNL cross sections required larger $C_5^A(0)$ values. Our preference at the time for ANL data was due to the fact that they provided absolute q^2 -differential cross sections (as opposed to BNL where only the shape was given) evaluated with a kinematical cut appropriate for our model. BNL cross section values are larger and they seemed to be incompatible with ANL ones. As it has recently been demonstrated in Ref. [8], where a reanalysis of both ANL and BNL data has been conducted, the discrepancies between the two datasets stem from their respective uncertainties in the neutrino flux normalization. In Ref. [5], apart from the ANL flux-averaged q^2 -differential $\nu_\mu p \rightarrow \mu^- p \pi^+$ cross section, we included in the fit the three lowest neutrino energy $\nu_\mu p \rightarrow \mu^- p \pi^+$ total cross sections from BNL and we considered the uncertainties on the neutrino flux normalizations as fully correlated systematic errors. Deuteron effects turned out to reduce the cross section by some 10% which agreed with previous estimates in Refs. [6, 9]. To compensate this reduction in the cross section a roughly 5% larger $C_5^A(0)$ value was needed. However, it was the consideration in the fit of BNL cross sections that was responsible for the larger change in $C_5^A(0)$. Assuming a simpler pure dipole form for C_5^A , we obtained $C_5^A(0) = 1.0 \pm 0.1$, a value closer to the GTR one¹.

In Ref. [10], and in order to extend the model to higher neutrino energies (up to 2 GeV) we added the contribution from the spin 3/2 nucleon $D_{13}(1520)$ resonance. This is the only resonance, apart from the Δ , that gives a significant contribution in that energy region [11]. The corresponding vector and axial form factors for the $N \rightarrow D_{13}$ transition current were taken respectively from fits to results in Refs. [12] and [13], respectively. A full account of the direct and crossed $D_{13}(1520)$ contributions can be found in the appendix of Ref. [10].

Finally, in Ref. [14] we partially unitarized our model by imposing Watson's theorem. This theorem is a result of unitarity and time-reversal invariance and it implies that the phase of the electro or weak pion production amplitude is fully determined by the strong $\pi N \rightarrow \pi N$ interaction elastic phase shifts $[\delta_{L2J+1,2T+1}(W_{\pi N})]$. Imposing Watson restrictions in general is a difficult task, and thus in [14] we only paid attention to the dominant spin-3/2 isospin-3/2 positive-parity amplitude, where the direct excitation of the $\Delta(1232)$ resonance occurs. Following the procedure suggested by M.G. Olsson in Ref. [15], we introduced independent vector and axial phases (two-dimensional functions of q^2 and $W_{\pi N}$) to correct the interference between the dominant direct Δ term and the non-resonant background. These extra phases were fixed by requiring that the total (resonance plus background contributions) amplitude in this dominant channel had the correct phase $\delta_{P_{33}}(W_{\pi N})$. Since this was not possible in a consistent way for all different terms that contribute to the P_{33} amplitude in the multipolar expansion, we unitarized only the dominant vector and axial multipoles. Within this scheme we performed two different fits in Ref. [14]. For Fit A we used the same input data as in Ref. [5] and described above. As a consequence of imposing Watson's theorem the interference between the dominant direct Δ contribution and the background terms changed, and as a result a larger value (1.12 ± 0.11)

¹ In some fits carried out in [5], we unsuccessfully relaxed Adler's constraints exploring the possibility of extracting some direct information on $C_{3,4}^A(0)$. We showed there that, the available low-energy data cannot effectively disentangle the different form-factor contributions.

for $C_5^A(0)$, in agreement now with the GTR prediction, was obtained. For Fit B we used the results of Ref. [8]. As already mentioned, the authors of Ref. [8] reanalyzed ANL and BNL experiments producing data on the ratio between the $\sigma(\nu_\mu p \rightarrow \mu^- p \pi^+)$ and the charged current quasi-elastic (CCQE) cross sections measured in deuterium. In this way, the flux uncertainties present in the experiments cancel. They found a good agreement between the two experiments for these ratios. Then, by multiplying the cross section ratio by the theoretical CCQE cross section on the deuteron², which is well under control, flux normalization independent pion production cross sections were extracted. We took advantage of these developments and for Fit B in Ref. [14] we considered the new data points. Since no cut in $W_{\pi N}$ was imposed on this new data we only used total cross sections for neutrino energies below 1 GeV. Besides, to constrain the q^2 dependence of the C_5^A form factor, we also fitted the shape of the original ANL flux-folded $d\sigma/dq^2$ distribution, where a $W_{\pi N} < 1.4$ GeV cut was implemented. For this fit we obtained $C_5^A(0) = 1.14 \pm 0.07$, similar to the result from Fit A. The quality of the fit, the predictions for cross sections in other channels, as well as the values of the Olsson phases needed to satisfy Watson's theorem were very similar in Fits A and B.

The agreement of the theoretical predictions with data was also good for the total cross sections in other channels with one notable exception, the $\nu_\mu n \rightarrow \mu^- n \pi^+$ reaction shown in Fig. 1, where theoretical predictions lie below experimental points. This is a common problem to other models [17–20]³. A special mention deserves the dynamical model of photo-, electro- and weak pion production initially derived in Ref. [17], and that has been recently further refined and extended to incorporate N^* resonances and a larger number of meson-baryon states [18, 19]. Despite its theoretical and phenomenological robust support, satisfying unitary constraints and fulfilling thus Watson's theorem, this model provides also a poor description of the $\nu_\mu n \rightarrow \mu^- n \pi^+$ channel, comparable to that shown in Fig. 1.

FIG. 1. $\nu_\mu n \rightarrow \mu^- n \pi^+$ total cross section obtained with the parameters from fit B in Ref. [10] as compared to ANL [4] and BNL [7] data. ANL data and theoretical results include a cut $W_{\pi N} < 1.4$ GeV in the final pion-nucleon invariant mass. Experimental points include a systematic error due to flux uncertainties (assumed to be 20% for ANL and 10% for BNL data) which had been added in quadratures to the statistical ones. Theoretical bands correspond to the variation of the results when $C_5^A(0)$ changes within its error interval.

As can be deduced from the explicit expressions given in Ref. [1], the $\nu_\mu n \rightarrow \mu^- n \pi^+$ reaction gets a large contribution from the crossed Δ mechanism and thus it is very sensitive to the spin 1/2 components present in the Rarita-Schwinger (RS) covariant Δ propagator. Indeed, besides the Δ propagator, the numerical factors of the (direct and crossed) Δ mechanisms are $(\sqrt{3} \text{ \& \; } 1/\sqrt{3})$, $(-\sqrt{2/3} \text{ \& \; } \sqrt{2/3})$, and $(1/\sqrt{3} \text{ \& \; } \sqrt{3})$ for the $p\pi^+$, $p\pi^0$, and $n\pi^+$ channels, respectively⁴. Thus, isospin invariance implies that the largest (smallest) contribution of the crossed Δ mechanism occurs in the $n\pi^+$ ($p\pi^+$) channel, while the largest (smallest) contribution of the direct Δ mechanism in contrast is found in the $p\pi^+$ ($n\pi^+$) amplitude. The RS covariant propagator, with its lower spin components, is considered to be incorrect in Ref. [22] where the authors advocate the use of the pure spin 3/2 propagator of Behrends and Fronsdaal [23]. The opposite view is adopted in Ref. [24] where the pure spin 3/2 propagator is considered incorrect since it does not satisfy the appropriate Green function equation. In Ref. [25], it is argued that off-shell terms of lower spin can naturally appear in the construction of propagators, and such terms explain, for instance, the decay of a spinless pion through an intermediate vector meson, without violating the conservation law of angular momentum. It is only because the vector propagator has an off-shell spin 0 part that the charged pion can decay [24–26]. What is also true

² For that purpose they used the prediction from GENIE 2.9 [16].

³ Note that in Ref. [20] the theoretical predictions are below data when the cut $W_{\pi N} < 1.4$ GeV is implemented. Indeed, this work uses the SU(2) chiral model derived in Ref. [1], imposing GTR and including smaller contributions from other resonances different to the $\Delta(1232)$ and the $D_{13}(1520)$.

⁴ Note that the $p\pi^0$ coefficients quoted in a similar discussion in Ref. [14] were wrong by an overall $-1/\sqrt{2}$ factor.

is that those lower spin terms are always non-propagating giving rise to pure contact interactions. In Refs. [27–29] the approach is somewhat different. There, the authors arrive at a pure spin 3/2 contribution from the Δ propagator by selecting consistent couplings. These are derivative couplings that preserve the gauge invariance of the free massless spin 3/2 Lagrangian. In Ref. [29] it is shown how to obtain consistent couplings from inconsistent ones by just a redefinition of the spin 3/2 field. The difference amount to contact terms that in this approach are responsible for the contribution of the extra lower-spin degrees of freedom. However, as already acknowledged in Ref. [27], and very recently reanalyzed in Ref. [30], consistent couplings cannot be kept in the presence of electromagnetic interactions. This is so since any derivative on the Δ field gives rise through minimal substitution to a new non-derivative term.

Our approach to this problem is conceptually different, based on the perspective of an effective field theory, and it is motivated by the discussion in Ref. [29]. In this latter reference it is argued that i) the use of consistent or inconsistent couplings will provide the same physical predictions as far as all relevant contact terms allowed by the underlying symmetries are included in both cases, and ii) the strength of the contact terms will have to be fitted to experiment. According to this, in this work we propose a minimal modification of our model, in which the contact terms that derive from the spin 1/2 part of the Δ propagator are multiplied by an extra parameter (low energy constant), that will be fitted to data.

The work is organized as follows: In Sec. II we describe the $\Delta(1232)$ propagator used in Ref. [1], and show that it is a Green function of the RS equation of motion. We also give its decomposition into a spin 3/2 part plus the rest. The latter is a non-propagating spin 1/2 part that gives rise to contact interactions, at least in the limit of zero width. In Sec. III we describe the prescription of Ref. [29] to go from inconsistent to consistent couplings and show the effects of using consistent couplings in the evaluation of an amplitude where the Δ appears as an intermediate state. The extension (modification) of our model is described in Sec. IV, and the new results are presented in Sec. V. We also give results for pion photo-production. The amplitude for this latter process derives from the vector part of our model for weak pion production, and it is described in the appendix. Finally in Sec. VI we summarize the main conclusions of this work.

II. RARITA-SCHWINGER PROPAGATOR

The RS Lagrangian of the free massive spin 3/2 reads [29] (we particularize for the $\Delta(1232)$ resonance case),

$$\mathcal{L}_{\text{RS}} = \bar{\Psi}_\mu \Lambda^{\mu\nu} \Psi_\nu, \quad \Lambda^{\mu\nu} = (\gamma^{\mu\nu\alpha} i\partial_\alpha - M_\Delta \gamma^{\mu\nu}) = \frac{1}{2} \{(i\partial - M_\Delta), \gamma^{\mu\nu}\}_+ \quad (1)$$

where Ψ_μ represents the RS field for the Δ and

$$\gamma_{\beta\nu\alpha} = \frac{1}{2} \{\gamma_{\beta\nu}, \gamma_\alpha\}_+ = -i\epsilon_{\beta\nu\alpha\rho} \gamma^\rho \gamma_5, \quad \gamma_{\beta\nu} = \frac{1}{2} [\gamma_\beta, \gamma_\nu]. \quad (2)$$

with $\epsilon_{0123} = +1$ and $g^{\mu\nu} = (1, -1, -1, -1)$. The Lagrangian in Eq. (1) corresponds to the parameter $A = -1$ in the discussion of Eq. (2) of Ref. [24] (note that the physical properties of the free field are independent of this parameter). The Euler-Lagrange equation read,

$$\Lambda^{\mu\nu} \Psi_\nu = (\gamma^{\mu\nu\alpha} i\partial_\alpha - M_\Delta \gamma^{\mu\nu}) \Psi_\nu = -[(i\partial - M_\Delta) g^{\mu\nu} + \gamma^\mu (i\partial + M_\Delta) \gamma^\nu - i(\gamma^\mu \partial^\nu + \partial^\mu \gamma^\nu)] \Psi_\nu = 0 \quad (3)$$

which lead to the set of equations

$$(i\partial - M_\Delta) \Psi_\nu = 0, \quad \partial^\nu \Psi_\nu = 0, \quad \gamma^\nu \Psi_\nu = 0 \quad (4)$$

The corresponding RS propagator is

$$G_{\mu\nu}(p_\Delta) = \frac{P_{\mu\nu}(p_\Delta)}{p_\Delta^2 - M_\Delta^2 + iM_\Delta \Gamma_\Delta} \quad (5)$$

$$P^{\mu\nu}(p_\Delta) = -(\not{p}_\Delta + M_\Delta) \left[g^{\mu\nu} - \frac{1}{3} \gamma^\mu \gamma^\nu - \frac{2}{3} \frac{p_\Delta^\mu p_\Delta^\nu}{M_\Delta^2} + \frac{1}{3} \frac{p_\Delta^\mu \gamma^\nu - p_\Delta^\nu \gamma^\mu}{M_\Delta} \right] \quad (6)$$

In the zero width limit ($\Gamma_\Delta = 0$, i.e., when dealing with a stable particle), the above propagator gives the Green function of the RS equation of motion

$$\Lambda_{\alpha\beta} G_\delta^\beta(x) = g_{\alpha\delta} \delta^4(x), \quad (7)$$

with $G^{\mu\nu}(x)$ the Fourier's transform of $G^{\mu\nu}(p_\Delta)$. This result follows trivially from

$$(\gamma_{\mu\nu\alpha} p_\Delta^\alpha - M_\Delta \gamma_{\mu\nu}) P^{\nu\beta}(p_\Delta) = (p_\Delta^2 - M_\Delta^2) g_\mu^\beta, \quad (8)$$

which can be obtained after a little of Dirac algebra.

The $P^{\mu\nu}$ operator can be re-written as [28]

$$P_{\mu\nu}(p) = P_{\mu\nu}^{\frac{3}{2}}(p) + (p^2 - M_\Delta^2) \left[\frac{2}{3M_\Delta^2} (\not{p} + M_\Delta) \frac{p_\mu p_\nu}{p^2} - \frac{1}{3M_\Delta} \left(\frac{p^\rho p_\nu \gamma_{\mu\rho}}{p^2} + \frac{p^\rho p_\mu \gamma_{\rho\nu}}{p^2} \right) \right], \quad (9)$$

with

$$P_{\mu\nu}^{\frac{3}{2}}(p) = -(\not{p} + M_\Delta) \left[g_{\mu\nu} - \frac{1}{3} \gamma_\mu \gamma_\nu - \frac{1}{3p^2} (\not{p} \gamma_\mu p_\nu + p_\mu \gamma_\nu \not{p}) \right]. \quad (10)$$

$P_{\mu\nu}^{\frac{3}{2}}(p)$ satisfies the relations

$$0 = [\not{p}, P_{\mu\nu}^{\frac{3}{2}}(p)] = p^\mu P_{\mu\nu}^{\frac{3}{2}}(p) = P_{\mu\nu}^{\frac{3}{2}}(p) p^\nu = \gamma^\mu P_{\mu\nu}^{\frac{3}{2}}(p) = P_{\mu\nu}^{\frac{3}{2}}(p) \gamma^\nu, \quad P_{\mu\nu}^{\frac{3}{2}}(p) [P^{\frac{3}{2}}(p)]^{\nu\rho} = -(\not{p} + M_\Delta) [P^{\frac{3}{2}}(p)]_\mu^\rho \quad (11)$$

from where one concludes that $P_{\mu\nu}^{\frac{3}{2}}$ is the spin-3/2 projection operator.

Finally we would like to stress that Eq. (9) shows that in the RS propagator of Eq. (5), only the spin-3/2 degrees of freedom propagate, while the controversial spin-1/2 contributions give rise to contact background terms. (This is strictly true in the zero width limit where the factor $(p^2 - M_\Delta^2)$ in Eq. (9) cancels the denominator of the Δ -propagator.) As we will discuss below, the total strength of the contact terms is undetermined in an effective chiral expansion, and it needs to be determined from experiment.

III. CONSISTENT Δ INTERACTIONS: THE PRESCRIPTION OF REF. [29]

The kinetic term of the free RS Lagrangian in Eq. (1) is invariant under the gauge transformation

$$\Psi_\mu(x) \rightarrow \Psi_\mu(x) + \partial_\mu \epsilon(x), \quad (12)$$

with $\epsilon(x)$ a spinor. It is argued in Refs. [27, 28] that any interaction term that respects this symmetry does not change the degrees of freedom content of the free theory, where the constraints on $\Psi_\mu(x)$ guarantee that it indeed describes spin 3/2 particles. Couplings respecting this symmetry are called consistent ones. In the case of linear couplings of the form

$$\mathcal{L}_{\text{int}} = g \bar{\Psi}_\beta J^\beta + h.c., \quad (13)$$

where J^μ is any current coupled to Δ , the invariance of the Lagrangian under the gauge transformation requires the current J^μ to be conserved. If that is not the case the coupling is called inconsistent. The transformation of this latter coupling into a consistent one can be achieved via a redefinition of the Δ field

$$\Psi_\mu \rightarrow \Psi_\mu + g \xi_\mu. \quad (14)$$

This transformation modifies the linear coupling

$$\mathcal{L}'_{\text{int}} = g \bar{\Psi}_\beta (J^\beta + \Lambda^{\beta\nu} \xi_\nu) + h.c. \quad (15)$$

and gives rise to an additional contact interaction Lagrangian, \mathcal{L}_C , independent of the RS field (see Ref. [29] for details on \mathcal{L}_C). By selecting

$$\xi_\mu = (M_\Delta \gamma^{\mu\nu})^{-1} J^\nu = -\frac{1}{M_\Delta} \mathcal{O}_{\mu\nu}^{(-1/3)} J^\nu, \quad (16)$$

where

$$\mathcal{O}_{\nu\mu}^{(x)} = g_{\nu\mu} + x \gamma_\nu \gamma_\mu, \quad (17)$$

one has that the new total current coupled to the Δ is

$$\mathcal{J}^\beta = J^\beta + \Lambda^{\beta\nu} \xi_\nu = \gamma^{\beta\nu\alpha} i \partial_\alpha \xi_\nu = -\frac{i}{M_\Delta} \gamma^{\beta\nu\alpha} \mathcal{O}_{\nu\rho}^{(-1/3)} \partial_\alpha J^\rho, \quad (18)$$

which is indeed conserved.

Apart from a total divergence of no consequence, Eq. (15) can be rewritten as

$$\mathcal{L}'_{\text{int}} = i \frac{g}{M_\Delta} \partial_\alpha \bar{\Psi}_\beta \gamma^{\alpha\beta\nu} \mathcal{O}_{\nu\rho}^{(-1/3)} J^\rho + h.c. \quad (19)$$

This is the prescription described in Ref. [29] to transform an inconsistent coupling into a consistent one. The description in terms of the original \mathcal{L}_{int} or the modified $\mathcal{L}'_{\text{int}} + \mathcal{L}_C$ Lagrangians is equivalent at the level of the S -matrix.

It is further argued in Ref. [29] that, within chiral perturbation theory (ChPT), any linear spin-3/2 coupling is acceptable. This is so since the additional \mathcal{L}_C contact terms, which provide the equivalence between inconsistent and consistent couplings, have to be included in both situations with arbitrary coefficients that have to be fitted to some experimental input. Thus, it is only the value of the coefficients of the contact terms that change. In this respect, the spin-1/2 contributions in the RS propagator, that give rise to pure contact terms, can be totally eliminated and their effects reabsorbed into the values of some of the low-energy-constants of the additional zero-range couplings. According to Ref. [29], it is preferable the use of consistent interaction terms, supplemented with the adequate contact interactions, in the analysis of the separate contributions due to spin 3/2 degrees of freedom versus the rest.

To see the effect of the use of consistent interactions, let us consider a process driven by the excitation of the Δ and its subsequent decay into some final particles. This mechanism is depicted in the left panel of Fig. 2 and it is determined by the currents \bar{K}^ϵ and J^ρ that couple the Δ to the initial and final particles, respectively, and that we assume to be of the inconsistent type. In the zero width limit, the amplitude for the process would be

FIG. 2. Left: Reaction mechanism where a Δ is excited and later on it decays into some final particles. Right: Contact term that accounts for the difference when the diagram depicted in the left panel is evaluated using consistent or inconsistent Δ couplings.

$$T = g_1 g_2 \bar{K}^\epsilon \frac{P_{\epsilon\rho}}{p_\Delta^2 - M_\Delta^2} J^\rho, \quad (20)$$

while using the consistent currents \bar{K}^ϵ and J^ρ , one would get

$$T_{\text{consistent}} = g_1 g_2 \bar{K}^\epsilon \frac{P_{\epsilon\rho}}{p_\Delta^2 - M_\Delta^2} J^\rho \quad (21)$$

$$= g_1 g_2 \frac{p_{\Delta\eta} p_{\Delta\sigma}}{M_\Delta^2} \bar{K}^\epsilon \mathcal{O}_{\epsilon\mu}^{(-1/3)} \gamma^{\mu\eta\alpha} \frac{P_{\alpha\beta}}{p_\Delta^2 - M_\Delta^2} \gamma^{\beta\sigma\nu} \mathcal{O}_{\nu\rho}^{(-1/3)} J^\rho \quad (22)$$

$$= g_1 g_2 \bar{K}^\epsilon \frac{p_\Delta^2}{M_\Delta^2} \frac{P_{\epsilon\rho}^{\frac{3}{2}}}{p_\Delta^2 - M_\Delta^2} J^\rho. \quad (23)$$

This result follows from the antisymmetry of the $\gamma^{\mu\eta\alpha}$ tensor that guaranties that,

$$\begin{aligned} p_{\Delta\eta} p_{\Delta\sigma} \mathcal{O}_{\epsilon\mu}^{(-1/3)} \gamma^{\mu\eta\alpha} P_{\alpha\beta} \gamma^{\beta\sigma\nu} \mathcal{O}_{\nu\rho}^{(-1/3)} &= p_{\Delta\eta} p_{\Delta\sigma} \mathcal{O}_{\epsilon\mu}^{(-1/3)} \gamma^{\mu\eta\alpha} P_{\alpha\beta}^{\frac{3}{2}} \gamma^{\beta\sigma\nu} \mathcal{O}_{\nu\rho}^{(-1/3)} \\ &= -p_{\Delta\eta} p_{\Delta\sigma} \mathcal{O}_{\epsilon\mu}^{(-1/3)} \gamma^{\mu\eta\alpha} (p_\Delta + M_\Delta) \mathcal{O}_{\alpha\beta}^{(-1/3)} \gamma^{\beta\sigma\nu} \mathcal{O}_{\nu\rho}^{(-1/3)}, \end{aligned} \quad (24)$$

and some further Dirac algebra⁵.

⁵ In Eq. (24), the $g_{\epsilon\mu}$ tensor in $\mathcal{O}_{\epsilon\mu}^{(-1/3)}$ gives the final result, $p_\Delta^2 P_{\epsilon\rho}^{\frac{3}{2}}$, while the $\gamma_\epsilon \gamma_\mu$ part produces an antisymmetric tensor in the η and σ indices whose contribution vanishes when contracted with the symmetric $p_{\Delta\eta} p_{\Delta\sigma}$ term.

By comparing Eqs. (20) and (23), we see that the use of consistent couplings induces the replacement

$$P_{\epsilon\rho} \leftrightarrow \frac{p_\Delta^2}{M_\Delta^2} P_{\epsilon\rho}^{\frac{3}{2}} \quad (25)$$

in the Feynman amplitudes. Note that the factor p_Δ^2 in front of $P_{\epsilon\rho}^{\frac{3}{2}}$ corrects for the ill-defined infra-red behaviour of the latter operator. From Eq. (9) we see that $P_{\epsilon\rho}$ and $P_{\epsilon\rho}^{\frac{3}{2}}$ differ in terms that vanish on-shell ($p_\Delta^2 = M_\Delta^2$),

$$P_{\epsilon\rho} - \frac{p_\Delta^2}{M_\Delta^2} P_{\epsilon\rho}^{\frac{3}{2}} = (p_\Delta^2 - M_\Delta^2) \delta P_{\epsilon\rho}(p_\Delta) \quad (26)$$

$$\delta P_{\epsilon\rho}(p_\Delta) = \frac{1}{M_\Delta^2} (\not{p}_\Delta + M_\Delta) \left(g_{\epsilon\rho} - \frac{1}{3} \gamma_\epsilon \gamma_\rho \right) + \frac{1}{3M_\Delta^2} (p_\Delta^\epsilon \gamma_\rho - p_\Delta^\rho \gamma_\epsilon) \quad (27)$$

and thus the amplitudes T and $T_{consistent}$ differ in a contact (non-propagating) term δT ,

$$T = T_{consistent} + \delta T, \quad \delta T = g_1 g_2 \bar{K}^\epsilon \delta P_{\epsilon\rho} J^\rho \quad (28)$$

The discussion above amounts to admit that the actual size of a contact term like δT is in fact undetermined, since the contact terms that appear in the effective chiral expansion are not fixed, and need to be fitted to experiment. Hence the use of consistent or inconsistent Δ -couplings should not produce any difference, as long as the needed contact terms are phenomenologically determined.

1. The $\pi N \Delta$ coupling

For the case of the $\pi N \Delta$ coupling, in Ref. [1] we took

$$\mathcal{L}_{\pi N \Delta} = \frac{f^*}{m_\pi} \bar{\Psi}_\beta \vec{T}^\dagger \Psi \partial^\beta \vec{\phi} + h.c. \quad (29)$$

with f^* the strong coupling constant, m_π the pion mass, Ψ and $\vec{\phi}$ the nucleon and pion fields⁶, and \vec{T}^\dagger the isospin $1/2 \rightarrow 3/2$ transition operator defined such that its Wigner-Eckart reduced matrix element is equal to one. The Δ width that results from the above vertex, assuming an on-shell Δ at rest and with mass $W_{\pi N}$, i.e., $p_\Delta^\mu = (W_{\pi N}, \vec{0})$, is given by⁷,

$$\Gamma_{\Delta \rightarrow N\pi}(W_{\pi N}) = \frac{1}{6\pi} \left(\frac{f^*}{m_\pi} \right)^2 \frac{E + M}{2W_{\pi N}} k_\pi^3 \Theta(W_{\pi N} - M - m_\pi) \quad (30)$$

where M, E and k_π are the mass and energy of the final nucleon and the final pion momentum, respectively in the Δ rest frame. Using isospin averaged masses and the value $\Gamma_{\Delta \rightarrow N\pi}(M_\Delta) = 117 \text{ MeV}$ [31] we obtain $f^* = 2.15$ to be compared to the value 2.14 that we have been using so far. The use of a consistent coupling would lead to the inclusion of an additional multiplicative factor $W_{\pi N}^2/M_\Delta^2$.

To end this subsection, we would like to devote a few words to the use of a more general $\pi N \Delta$ interaction of the form [24]

$$\frac{f^*}{m_\pi} \bar{\Psi}_\beta \vec{T}^\dagger (g^{\beta\alpha} + z \gamma^\beta \gamma^\alpha) \Psi \partial_\alpha \vec{\phi} + h.c. \quad (31)$$

In diagrams with an intermediate Δ , and because $P_{\alpha\beta}^{\frac{3}{2}} \gamma^\beta = 0$, the z -term will always give rise to contact contributions which, as argued above, need to be phenomenologically determined. Hence, without loss of generality, one can ignore these off-shell terms as far as all relevant contact interactions are taken into account⁸.

⁶ In our convention $\phi = (\phi_x - i\phi_y)/\sqrt{2}$ creates a π^- from the vacuum or annihilates a π^+ , whereas the ϕ_z field creates or annihilates a π^0 .

⁷ In the expression of Eq. (45) of Ref. [1], the factor $(E + M)/2W_{\pi N}$ was approximated by $M/W_{\pi N}$.

⁸ In this context, the inconsistency between the free Δ propagator and the $\pi N \Delta$ Lagrangian referred to in Ref. [32] is no longer relevant.

IV. EXTENSION OF THE MODEL OF REFS. [1, 10, 14]

Aiming at improving the description of the $\nu_\mu n \rightarrow \mu^- n \pi^+$ channel, we open the possibility of supplementing the model of Refs. [1, 10, 14] with some additional contact terms. To keep the model simple, we introduce just one undetermined low energy constant (LEC), c , that enters in a modification of the Δ -propagator compatible with ChPT,

$$\frac{P_{\mu\nu}(p_\Delta)}{p_\Delta^2 - M_\Delta^2} \rightarrow \frac{P_{\mu\nu}(p_\Delta) + c \left(P_{\mu\nu}(p_\Delta) - \frac{p_\Delta^2}{M_\Delta^2} P_{\mu\nu}^{\frac{3}{2}}(p_\Delta) \right)}{p_\Delta^2 - M_\Delta^2} = \frac{P_{\mu\nu}(p_\Delta)}{p_\Delta^2 - M_\Delta^2} + c \delta P_{\mu\nu}(p_\Delta) \quad (32)$$

with the operator $\delta P_{\mu\nu}$ defined in Eq. (27). The introduction of this LEC induces two new terms in the model that come from the direct (Δ P) and crossed Δ pole (C Δ P) amplitudes.

So far, the values $c = 0$ and $c = -1$ would correspond to the use of inconsistent and consistent Δ -couplings. We now reintroduce in the denominator of the propagator in Eq. (32) the imaginary part $iM_\Delta\Gamma_\Delta$, where for Γ_Δ we use Eq.(30) with the new f^* value. Note that the width is zero for the C Δ P term, while we expect the direct Δ P contribution to be largely dominated by the resonant propagator, being there the influence of the $\delta P_{\mu\nu}$ term quite small. However, we foresee that the contribution of this latter term could be relevant in the C Δ P amplitude, because in that case the Δ is largely off-shell.

It is worth stressing that the non-diagonal GTR is not affected by the changes and it predicts

$$C_5^A(0) = \sqrt{\frac{2}{3}} \frac{f_\pi}{m_\pi} f^*, \quad (33)$$

that for $f_\pi = 93.2 \text{ MeV}$ and the isospin averaged m_π value that we use results in $C_5^A(0) = 1.19$.

In principle one could also modify the $D_{13}(1520)$ terms included in our model (see Ref. [10]) along the lines described above and introduce an extra parameter. However, since the $D_{13}(1520)$ exchange contributions play a minor role, the effect of these latter modifications would be much less important and we shall ignore them.

With the modification in the Δ contributions, we repeat the Fit B carried out in Ref. [14]. In order to increase the sensitivity on the new c parameter, we now also include in the fit data for the $\nu_\mu n \rightarrow \mu^- n \pi^+$ reaction. We thus minimize the following χ^2

$$\chi^2 = \left\{ \sum_{i \in \text{ANL}} \left(\frac{\beta d\sigma/dQ_i^2|_{\text{exp}} - d\sigma/dQ_i^2|_{\text{th}}}{\beta \Delta(d\sigma/dQ_i^2|_{\text{exp}})} \right)^2 + \sum_{i \in \text{ANL}} \left(\frac{\sigma_i|_{\text{exp}} - \sigma_i|_{\text{th}}}{\Delta(\sigma_i|_{\text{exp}})} \right)^2 + \sum_{i \in \text{BNL}} \left(\frac{\sigma_i|_{\text{exp}} - \sigma_i|_{\text{th}}}{\Delta(\sigma_i|_{\text{exp}})} \right)^2 \right\}_{\nu_\mu p \rightarrow \mu^- p \pi^+} \quad (34)$$

$$+ \left\{ \sum_{i \in \text{ANL}} \left(\frac{\sigma_i|_{\text{exp}} - \sigma_i|_{\text{th}}}{\Delta(\sigma_i|_{\text{exp}})} \right)^2 \right\}_{\nu_\mu n \rightarrow \mu^- n \pi^+}. \quad (35)$$

The $d\sigma/dQ^2$ differential cross section values are the flux averaged measurements carried out at (ANL) [4] and they contain a $W_{\pi N} < 1.4 \text{ GeV}$ cut in the final pion-nucleon invariant mass. This dataset serves the purpose of constraining the q^2 dependence of the $C_5^A(q^2)$ axial form factor for which we assume a dipole form

$$C_5^A(q^2) = \frac{C_5^A(0)}{(1 - q^2/M_{A\Delta}^2)^2}. \quad (36)$$

The role played by the parameter β is to allow fitting only the shape of this distribution. The total $\nu_\mu p \rightarrow \mu^- p \pi^+$ ANL and BNL cross sections included in the fit are collected in Table II of Ref. [14]. They have been taken from the reanalysis of Ref. [8], where flux uncertainties in the original ANL and BNL data have been eliminated. Since they do not include a cut in $W_{\pi N}$, we only consider cross sections for neutrino energies $E_\nu \leq 1 \text{ GeV}$. Finally, for the total $\nu_\mu n \rightarrow \mu^- n \pi^+$ cross section, we take also the results of the reanalysis of the ANL data conducted in Ref. [33] and shown in Table I. In this latter case the data do contain a $W_{\pi N} < 1.4 \text{ GeV}$ cut. As in Ref. [14] we consider deuterium effects and Adler's constraints ($C_3^A = 0$, $C_4^A = -C_5^A/4$) on the axial form factors. Besides, Olsson's approximate implementation of Watson's theorem, as described in Ref. [14], is also taken into account.

TABLE I. $\nu_\mu n \rightarrow \mu^- n \pi^+$ ANL cross sections (in units of 10^{-38} cm²) taken from the reanalysis of Ref. [33]. A $W_{\pi N} < 1.4$ GeV cut has been applied to obtain the data.

E_ν (GeV)	$\sigma _{\text{exp}}$	$\Delta(\sigma _{\text{exp}})$	Exp.

V. RESULTS

A. Pion production by neutrinos

The best fit parameters resulting from the new fit are

$$C_5^A(0) = 1.18 \pm 0.07, \quad M_{A\Delta} = 950 \pm 60 \text{ MeV}, \quad c = -1.11 \pm 0.21 \quad (37)$$

and $\beta = 1.23 \pm 0.08$. The new $\chi^2/dof = 1.1$ is dominated by the $\nu_\mu n \rightarrow \mu^- n \pi^+$ reaction that gives rise to about 75% of the total. $C_5^A(0)$ is now larger by 3.5% than that found in Ref. [14], and it is in excellent agreement with the GTR value. The β parameter is a measure of the neutrino flux uncertainty in the ANL experiment. Its value is in agreement with the 20% uncertainty assumed for our Fit A in Ref. [14] and the fits in Refs. [5, 6].

In Fig. 3 we compare the fitted data and the new theoretical results. For comparison we also show the results from Fit B carried out in Ref. [14]. The shape for the flux averaged differential cross section⁹ $d\sigma/dQ^2$ $\nu_\mu p \rightarrow \mu^- p \pi^+$ is shown in the upper left panel. Both fits give almost identical results. For the total $\nu_\mu p \rightarrow \mu^- p \pi^+$ cross section, depicted in the upper right panel, some minor differences can be seen for the larger neutrino energies.

In the lower panel we show the $\nu_\mu n \rightarrow \mu^- n \pi^+$ cross section. The new theoretical results are very different from the ones obtained from Fit B in Ref. [14], and they are now in much better agreement with experimental data. The modifications introduced in the Δ contributions, that amount to the introduction of new contact terms controlled by the fitted LEC c , are crucial for this. Without those one can not reproduce the $\nu_\mu n \rightarrow \mu^- n \pi^+$ cross sections without worsening the agreement with data in other channels.

Results for the total $\nu_\mu n \rightarrow \mu^- p \pi^0$ and $\nu_\mu n \rightarrow \nu_\mu p \pi^-$ cross sections are given in Fig. 4. We find a good agreement with data and only very minor differences with the results obtained from Fit B carried out in Ref. [14].

The brown and gray theoretical bands in Figs. 3 and 4 show the sensitivity of the predicted cross sections to the errors on the the best-fit parameters $C_5^A(0)$ and the LEC c , respectively. In this latter case, only the $\nu_\mu n \rightarrow \mu^- n \pi^+$ channel is strongly affected when varying c . This was not unexpected, since the $\nu_\mu n \rightarrow \mu^- n \pi^+$ cross section has a large contribution from the C Δ P amplitude and thus it is very sensitive to the spin 1/2 part of the Δ propagator, which strength is now controlled by the parameter c .

The Olsson phases needed to satisfy Watson's theorem are presented in Fig. 5. We have selected the scales in order to allow a direct comparison with those obtained in Ref. [14], which are shown in Figure 3 of that reference. We now find much smaller values, always below 20° , and at the Δ -peak (left panel in Fig. 5) axial (vector) phases remain quite small and below 5° (10°) for the whole range ($[0, 2, 5]$ GeV²) of Q^2 -values shown in the plot. This means that the present model without the phases is closer to satisfying unitarity than the one in Ref. [14].

Finally, we pay attention to the best-fit value quoted in Eq. (37) for the LEC c . It is compatible with -1 , within errors, but however we should point out that $c = -1$ does not correspond exactly to a consistent coupling. This is

⁹ Note $Q^2 = -q^2$.

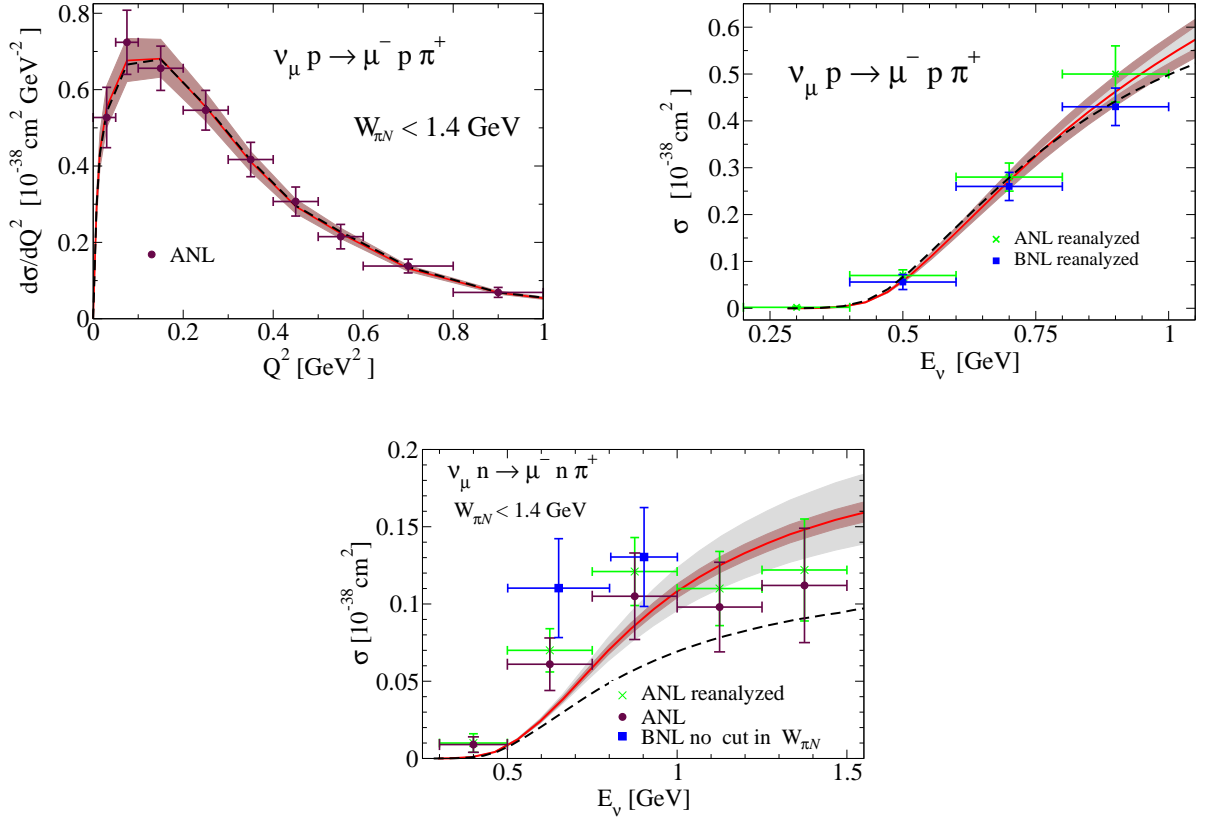

FIG. 3. Theoretical predictions for the shape of the flux averaged differential $d\sigma/dQ^2$ (upper left panel) and total $\nu_\mu p \rightarrow \mu^- p \pi^+$ (upper right panel) and $\nu_\mu n \rightarrow \mu^- n \pi^+$ (bottom panel) cross sections compared to data from ANL [4] (upper left panel) and the reanalysis of Ref. [8] (upper right panel) and Ref. [33] (bottom panel). In the bottom panel we also show the original ANL [4] and BNL [7] data. Red solid and black dashed lines show the results obtained in this work and those derived from Fit B of Ref. [14], respectively. In the upper left and bottom panels, ANL data (both original and reanalyzed) and theoretical results include a $W_{\pi N} < 1.4 \text{ GeV}$ cut in the final pion-nucleon invariant mass. Brown (gray) theoretical bands account for the variation of the results when $C_5^A(0)$ (LEC c) changes within its error interval given in Eq. (37). ANL reanalyzed cross sections have no systematic errors due to flux uncertainties. Besides, theoretical results in the upper left panel have been divided by $\beta = 1.23$, accounting for flux uncertainties [see Eq. (35)]. Deuteron effects have been taken into account as explained in Ref. [5].

because of the Δ -width, and thus even for $c = -1$, we have

$$\frac{P_{\mu\nu}}{p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta} - \delta P_{\mu\nu}(p_\Delta) = \frac{P_{\mu\nu} - (p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta) \delta P_{\mu\nu}(p_\Delta)}{p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta} \quad (38)$$

$$= \frac{P_{\mu\nu} - \frac{p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta}{p_\Delta^2 - M_\Delta^2} \left(P_{\mu\nu} - \frac{p_\Delta^2}{M_\Delta^2} P_{\mu\nu}^{\frac{3}{2}} \right)}{p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta} \quad (39)$$

$$= \frac{p_\Delta^2}{M_\Delta^2} \frac{P_{\mu\nu}^{\frac{3}{2}}}{p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta} - \frac{iM_\Delta\Gamma_\Delta}{p_\Delta^2 - M_\Delta^2} \frac{P_{\mu\nu} - \frac{p_\Delta^2}{M_\Delta^2} P_{\mu\nu}^{\frac{3}{2}}}{p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta}. \quad (40)$$

The first term in Eq. (40) corresponds to the prescription for consistent interactions advocated in Refs. [27–29]. The second one, that vanishes for the $C\Delta P$ amplitude, provides complex corrections to the direct Δ contribution, which induce changes in the Olsson phases. Indeed, we have checked that if the second term in Eq. (40) is neglected, one finds also an improved description of the $\nu_\mu n \rightarrow \mu^- n \pi^+$ data, as compared to the $c = 0$ case, and just a bit worse than that presented here in Fig. 3. However, the needed Olsson phases turn out to be larger than those depicted in Fig. 5, being only slightly different to the ones found in Ref. [14], where the LEC c was set to zero.

Note that the p_Δ^2/M_Δ^2 factor, in front of the first term of Eq. (40), drastically suppresses the $C\Delta P$ contribution, because in this mechanism the Δ is largely off-shell, with p_Δ^2 much smaller (in modulus) than M_Δ^2 .

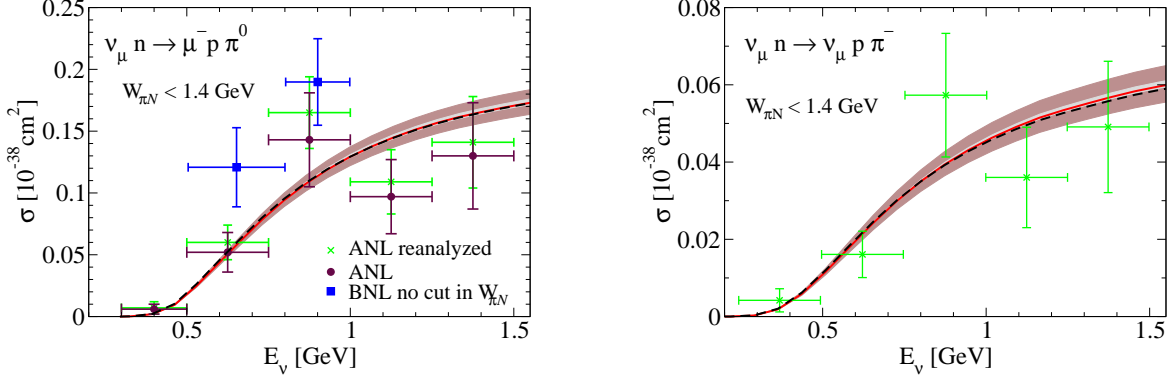

FIG. 4. Total $\nu_\mu n \rightarrow \mu^- p \pi^0$ (left) and $\nu_\mu n \rightarrow \nu_\mu p \pi^-$ (right) cross sections. Red solid and black dashed lines show the results obtained in this work and those derived from Fit B of Ref. [14], respectively. Experimental cross sections in the left panel have been taken from Ref. [4] (ANL), Ref. [7] (BNL) and Ref. [33] (ANL reanalyzed), while in the right panel the data have been taken from Ref. [21]. Theoretical results, ANL and ANL reanalyzed cross sections include a $W_{\pi N} < 1.4$ GeV cut in the final pion-nucleon invariant mass. Experimental errors and theoretical bands have been evaluated as described in the captions of Figs. 1 and 3. ANL reanalyzed data have no systematic errors due to flux uncertainties. Deuteron effects have been taken into account as explained in Ref. [5].

FIG. 5. Olsson phases from the fit carried out in this work. Left panel: Ψ_V and Ψ_A at the Δ peak as a function of $Q^2 = -q^2$. Middle and right panels: Ψ_V and Ψ_A as a function of the Δ invariant mass $W_{\pi N}$ for different Q^2 values, respectively.

B. Pion photo-production

Since in Ref. [14] we showed results for pion photo-production, it is relevant to see also for this case the effect of the modification introduced in the Δ propagator. Amplitudes for pion photo-production derive directly from the vector part of our model for weak pion production by neutrinos and they are extensively discussed in the appendix. As for the case of neutrino production, the model is also partially unitarized by imposing Watson's theorem on the dominant vector multipole, now evaluated at $q^2 = 0$. What we will show are pure predictions of the model without any readjustment of parameters or vector form factors. In Fig. 6 we present results for total cross sections that we compare to data taken from the George Washington University SAID database [35]. On the theoretical side, we compare the predictions obtained with the present model (red solid lines) with the results obtained without the modification of the spin 1/2 component of the Δ propagator (black dashed lines), the latter corresponding to setting $c = 0$. The description of the data is better in the current modified case, with c close to -1 . The theoretical bands show the sensitivity of the results with respect to the c parameter, when it is varied within the errors quoted in Eq. (37). To get a better reproduction of the cross sections above the Δ resonance region, the model would have to be enlarged by the addition of extra resonance contributions relevant for the case of electro- or photo-production.

FIG. 6. Total $\gamma p \rightarrow n\pi^+$ (upper left), $\gamma p \rightarrow p\pi^0$ (upper right) and $\gamma n \rightarrow p\pi^-$ (bottom) cross sections as a function of the photon energy in the laboratory frame. Red solid and black dashed lines show the predictions from the model presented in this work (see the appendix) and the results obtained without the modification of the spin 1/2 component of the Δ propagator ($c = 0$). Cross sections have been taken from the George Washington University SAID database [35]. Theoretical uncertainty bands account for the variation of the results when the parameter c changes within its error interval given in Eq. (37).

VI. SUMMARY AND CONCLUSIONS

We have improved our model of Refs. [1, 10, 14] by including two extra contact terms. This has been motivated by the failure of present theoretical approaches to describe the $\nu_\mu n \rightarrow \mu^- n\pi^+$ total cross section data. As shown in Ref. [1], this channel has a large contribution from the $C\Delta P$ mechanism and it is thus very sensitive to the spin 1/2 components in the Δ propagator. This spin 1/2 part is non-propagating and it gives rise to contact terms. Contact terms appear naturally within effective field theories, and in particular in ChPT, as counter-terms with unknown strengths. Indeed, the coefficients of the contact terms have to be ultimately fitted to experiment. Aiming at keeping our model simple, we have just introduced only one new parameter, c , that controls the strength of the contact terms generated by the spin 1/2 part of the Δ propagator. To constraint its value, we have also included $\nu_\mu n \rightarrow \mu^- n\pi^+$ cross section data in the fit. The description of this channel considerably improves, without affecting the good results we had already obtained in Refs. [1, 14] for the other channels. Since the fitted value of c is compatible with -1 , we find that the crossed Δ pole amplitude is substantially suppressed and that consistent Δ couplings [27–29] are preferred. Besides, the new Olsson phases needed to satisfy Watson’s theorem are now much smaller than those obtained in Ref. [14] for the $c = 0$ case, indicating that the present version without the phases is closer to satisfying unitarity. Yet, the $C_5^A(0)$ is now larger by 3.5% than that found in Ref. [14], and it is in remarkable agreement with the GTR value.

We have also explored how this change in the Δ propagator affects our predictions for pion photo-production. We also find now a better agreement with experiment compared to the case where the LEC c was set to zero.

Finally, we should mention that effects of the final state interactions (FSI) on single pion production off the deuteron might induce corrections on the nucleon spectator approximation. This approximation is used to extract the pion production cross sections on the nucleon from the data on the deuteron. These effects have not been addressed in this

work. However, it has been argued [36, 37] that they might be of special relevance precisely in the $n\pi^+$ channel, and that the ANL and BNL data on the deuterium target might need a more careful analysis with the FSI's taken into account. For such a re-analysis to be meaningful, it will be mandatory to incorporate the kinematical cuts implemented in the old experiments to properly separate the three reaction channels ($p\pi^+$, $p\pi^0$ and $n\pi^+$), since these cuts were designed to minimize the corrections to the spectator hypothesis. Nevertheless, the existence of some FSI effects will not exclude the solution to the $n\pi^+$ puzzle offered here, and based on the possibility of adding phenomenological contact terms. It is certainly natural within the context of effective field theories.

Appendix A: Model for pion photo- and electro-production off the nucleon

Our model for pion photo or electroproduction off the nucleon derives directly from the vector part of that constructed for weak pion production by neutrinos. Thus, it includes all the contributions depicted in Fig. 7: the resonant direct and crossed $\Delta(1232)$ pole terms (ΔP and $C\Delta P$ respectively) and the background terms required by chiral symmetry. The latter ones include direct and crossed nucleon pole (labeled as NP and CNP), contact (CT) and pion-in-flight (PF) terms. Besides we also consider the direct and crossed $D_{13}(1520)$ pole terms (DP and CDP, respectively).

FIG. 7. Model $\gamma N \rightarrow N'\pi$ or $\gamma^* N \rightarrow N'\pi$ reactions. First row: Direct and crossed $\Delta(1232)$ pole terms. Second row: Direct and crossed nucleon pole terms. Third row: Contact and pion-in-flight terms. Fourth row: Direct and crossed D_{13} pole terms.

In the notation of Ref. [1], the quark level electromagnetic current is given by¹⁰

$$s_{\text{em}}^\mu = \frac{2}{3} \bar{\Psi}_u \gamma^\mu \Psi_u - \frac{1}{3} \bar{\Psi}_d \gamma^\mu \Psi_d - \frac{1}{3} \bar{\Psi}_s \gamma^\mu \Psi_s. \quad (\text{A1})$$

¹⁰ We ignore the contribution from heavy quarks.

This can be written as the sum of an isoscalar and an isovector pieces

$$s_{\text{em}}^\mu = s_{\text{em IS}}^\mu + s_{\text{em IV}}^\mu \quad (\text{A2})$$

$$s_{\text{em IS}}^\mu = \frac{1}{6} \bar{\Psi}_q \gamma^\mu \Psi_q - \frac{1}{3} \bar{\Psi}_s \gamma^\mu \Psi_s,$$

$$s_{\text{em IV}}^\mu = \frac{1}{\sqrt{2}} \bar{\Psi}_q \gamma^\mu \frac{\tau_0^1}{\sqrt{2}} \Psi_q \quad (\text{A3})$$

with $\Psi_q = \begin{pmatrix} \Psi_u \\ \Psi_d \end{pmatrix}$ and $\tau_0^1 = \tau_z$, where τ_x, τ_y, τ_z are the three Pauli matrices.

In the same notation the vector part of the charged weak current reads

$$V_{cc\pm}^\mu = \mp \bar{\Psi}_q \gamma^\mu \frac{\tau_{\pm 1}^1}{\sqrt{2}} \Psi_q \quad (\text{A4})$$

with $\tau_{\pm 1}^1 = \mp \frac{1}{\sqrt{2}}(\tau_x \pm i\tau_y)$. We could relate the matrix elements of the isovector part of the electromagnetic current with those of $V_{cc\pm}^\mu$. To that end, we express the physical nucleon-pion states in terms of states with well defined total isospin,

$$\begin{aligned} |p\pi^+\rangle &= -|N\pi; 3/2, 3/2\rangle, \\ |p\pi^0\rangle &= \sqrt{\frac{2}{3}}|N\pi; 3/2, 1/2\rangle + \frac{1}{\sqrt{3}}|N\pi; 1/2, 1/2\rangle, \\ |n\pi^+\rangle &= -\frac{1}{\sqrt{3}}|N\pi; 3/2, 1/2\rangle + \sqrt{\frac{2}{3}}|N\pi; 1/2, 1/2\rangle, \\ |n\pi^0\rangle &= \sqrt{\frac{2}{3}}|N\pi; 3/2, -1/2\rangle - \frac{1}{\sqrt{3}}|N\pi; 1/2, -1/2\rangle, \\ |p\pi^-\rangle &= \frac{1}{\sqrt{3}}|N\pi; 3/2, -1/2\rangle + \sqrt{\frac{2}{3}}|N\pi; 1/2, -1/2\rangle, \\ |n\pi^-\rangle &= |N\pi; 3/2, -3/2\rangle. \end{aligned} \quad (\text{A5})$$

and then we can obtain¹¹

$$\begin{aligned} \langle p\pi^+ | V_{cc+}^\mu(0) | p \rangle &= -\langle 3/2 \parallel V^\mu \parallel 1/2 \rangle, \\ \langle n\pi^+ | V_{cc+}^\mu(0) | n \rangle &= -\frac{1}{\sqrt{3}} \langle N\pi; 3/2, 1/2 | V_{cc+}^\mu(0) | n \rangle + \sqrt{\frac{2}{3}} \langle N\pi; 1/2, 1/2 | V_{cc+}^\mu(0) | n \rangle \\ &= -\frac{1}{3} \langle 3/2 \parallel V^\mu \parallel 1/2 \rangle - \frac{2}{3} \langle 1/2 \parallel V^\mu \parallel 1/2 \rangle, \end{aligned} \quad (\text{A7})$$

from where

$$\begin{aligned} \langle 3/2 \parallel V^\mu \parallel 1/2 \rangle &= -\langle p\pi^+ | V_{cc+}^\mu(0) | p \rangle, \\ \langle 1/2 \parallel V^\mu \parallel 1/2 \rangle &= -\frac{3}{2} \langle n\pi^+ | V_{cc+}^\mu(0) | n \rangle + \frac{1}{2} \langle p\pi^+ | V_{cc+}^\mu(0) | p \rangle. \end{aligned} \quad (\text{A8})$$

These two reduced matrix elements determine all matrix elements of the isovector part of the electromagnetic current. As an example we evaluate¹²

$$\begin{aligned} \langle p\pi^0 | s_{\text{em IV}}^\mu(0) | p \rangle &= \sqrt{\frac{2}{3}} \langle N\pi; 3/2, 1/2 | s_{\text{em IV}}^\mu(0) | p \rangle + \frac{1}{\sqrt{3}} \langle N\pi; 1/2, 1/2 | s_{\text{em IV}}^\mu(0) | p \rangle \\ &= -\frac{1}{\sqrt{2}} \left(\frac{2}{3} \langle 3/2 \parallel V^\mu \parallel 1/2 \rangle + \frac{1}{3} \langle 1/2 \parallel V^\mu \parallel 1/2 \rangle \right) \\ &= \frac{1}{2\sqrt{2}} \left(\langle p\pi^+ | V_{cc+}^\mu(0) | p \rangle + \langle n\pi^+ | V_{cc+}^\mu(0) | n \rangle \right). \end{aligned} \quad (\text{A9})$$

¹¹ For a tensor operator T_m^j we use the Wigner-Eckart theorem with the convention

$$\langle j_2 m_2 | T_m^j | j_1 m_1 \rangle = \langle j_1, j, j_2, m_1, m, m_2 \rangle \langle j_2 \parallel T^j \parallel j_1 \rangle, \quad (\text{A6})$$

with $\langle j_1, j, j_2, m_1, m, m_2 \rangle$ a Clebsch-Gordan coefficient and $\langle j_2 \parallel T^j \parallel j_1 \rangle$ the reduced matrix element.

¹² Note the factor $-\frac{1}{\sqrt{2}}$ difference in the definition of $s_{\text{em IV}}^\mu$ and V_{cc+}^μ .

Similarly,

$$\begin{aligned}\langle n\pi^+ | s_{\text{em IV}}^\mu(0) | p \rangle &= -\frac{1}{2} \left(\langle p\pi^+ | V_{cc+}^\mu(0) | p \rangle - \langle n\pi^+ | V_{cc+}^\mu(0) | n \rangle \right), \\ \langle n\pi^0 | s_{\text{em IV}}^\mu(0) | n \rangle &= \langle p\pi^0 | s_{\text{em IV}}^\mu(0) | p \rangle \\ \langle p\pi^- | s_{\text{em IV}}^\mu(0) | n \rangle &= -\langle n\pi^+ | s_{\text{em IV}}^\mu(0) | p \rangle.\end{aligned}\quad (\text{A10})$$

Since the Δ exchange contributions of Fig 7 are purely isovector, and denoting by j_{em}^μ the matrix elements of the electromagnetic current, we thus get¹³

$$\begin{aligned}j_{\text{em}}^\mu|_{\Delta\text{P}} &= i C_\gamma^{\Delta\text{P}} \frac{f^*}{m_\pi} \sqrt{3} k_\pi^\alpha \bar{u}(\vec{p}') \left[\frac{P_{\alpha\beta}(p_\Delta)}{p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta} + c \delta P_{\alpha\beta}(p_\Delta) \right] \Gamma_V^{\beta\mu}(p, q) u(\vec{p}), \\ p_\Delta = p + q, \quad C_\gamma^{\Delta\text{P}} &= \begin{pmatrix} \sqrt{2}/3 & \text{for } p \rightarrow p\pi^0 \\ -1/3 & \text{for } p \rightarrow n\pi^+ \\ \sqrt{2}/3 & \text{for } n \rightarrow n\pi^0 \\ 1/3 & \text{for } n \rightarrow p\pi^- \end{pmatrix}, \\ \Gamma_V^{\beta\mu}(p, q) &= \left[\frac{C_3^V}{M} (g^{\beta\mu} \not{q} - q^\beta \gamma^\mu) + \frac{C_4^V}{M^2} (g^{\beta\mu} q \cdot p_\Delta - q^\beta p_\Delta^\mu) + \frac{C_5^V}{M^2} (g^{\beta\mu} q \cdot p - q^\beta p^\mu) + C_6^V g^{\beta\mu} \right] \gamma_5, \quad p_\Delta = p + q\end{aligned}\quad (\text{A11})$$

$$\begin{aligned}j_{\text{em}}^\mu|_{\text{C}\Delta\text{P}} &= i C_\gamma^{\text{C}\Delta\text{P}} \frac{f^*}{m_\pi} \frac{1}{\sqrt{3}} k_\pi^\beta \bar{u}(\vec{p}') \hat{\Gamma}_V^{\mu\alpha}(p', q) \left[\frac{P_{\alpha\beta}(p_\Delta)}{p_\Delta^2 - M_\Delta^2 + iM_\Delta\Gamma_\Delta} + c \delta P_{\alpha\beta}(p_\Delta) \right] u(\vec{p}), \\ p_\Delta = p' - q, \quad C_\gamma^{\text{C}\Delta\text{P}} &= \begin{pmatrix} \sqrt{2} & \text{for } p \rightarrow p\pi^0 \\ 1 & \text{for } p \rightarrow n\pi^+ \\ \sqrt{2} & \text{for } n \rightarrow n\pi^0 \\ -1 & \text{for } n \rightarrow p\pi^- \end{pmatrix}, \quad \hat{\Gamma}_V^{\mu\alpha}(p', q) = \gamma^0 [\Gamma_V^{\alpha\mu}(p', -q)]^\dagger \gamma^0\end{aligned}\quad (\text{A12})$$

where q , p , k_π , and p' are the incoming photon and nucleon and the outgoing pion and nucleon four momenta.

To compute the non-resonant amplitudes, we pay attention to the electromagnetic current associated to the Lagrangian of the SU(2) non-linear σ model derived in Ref. [1]. It reads,

$$s_{\text{em}}^\mu = \bar{\Psi} \gamma^\mu \left(\frac{1 + \tau_z}{2} \right) \Psi + \frac{ig_A}{2f_\pi} \bar{\Psi} \gamma^\mu \gamma_5 (\tau_{-1}^1 \phi^\dagger + \tau_{+1}^1 \phi) \Psi + i (\phi^\dagger \partial^\mu \phi - \phi \partial^\mu \phi^\dagger) + \dots \quad (\text{A13})$$

with $g_A = 1.26$, $f_\pi = 93.2 \text{ MeV}$, Ψ and $\vec{\phi}$ the nucleon and pion fields already introduced in Subsect. III 1. We have only kept those terms contributing to one pion production in the absence of chiral loop corrections. Thus, within our framework, and besides the excitation of the Δ and the $N^*(1520)$, the model for the $\gamma N \rightarrow \pi N$ reaction would consist of direct and crossed nucleon pole, contact and pion-in-flight terms, as shown diagrammatically in Fig. 7. We see that neither the pion-in-flight nor the contact terms contribute for π^0 photo-production, which implies in turn that they are purely isovector. Thus we get for these two contributions

$$j_{\text{em}}^\mu|_{\text{CT}} = -i C_\gamma^{\text{CT}} \frac{g_A}{\sqrt{2}f_\pi} (F_1^p(q^2) - F_1^n(q^2)) \bar{u}(\vec{p}') \gamma^\mu \gamma_5 u(\vec{p}), \quad C_\gamma^{\text{CT}} = \begin{pmatrix} -1 & \text{for } p \rightarrow n\pi^+ \\ 1 & \text{for } n \rightarrow p\pi^- \end{pmatrix} \quad (\text{A14})$$

$$j_{\text{em}}^\mu|_{\text{PF}} = -i C_\gamma^{\text{PF}} \frac{g_A}{\sqrt{2}f_\pi} (F_1^p(q^2) - F_1^n(q^2)) \frac{2M(2k_\pi - q)^\mu}{(k_\pi - q)^2 - m_\pi^2} \bar{u}(\vec{p}') \gamma_5 u(\vec{p}), \quad C_\gamma^{\text{PF}} = \begin{pmatrix} -1 & \text{for } p \rightarrow n\pi^+ \\ 1 & \text{for } n \rightarrow p\pi^- \end{pmatrix} \quad (\text{A15})$$

For the proton and neutron Dirac electromagnetic form factors, $F_1^{p,n}$ we use the parametrization of Galster et al. [34], as we did in Ref. [1] for weak pion production.

¹³ The Feynman amplitude will be proportional to $e j_{\text{em}}^\mu \epsilon_\mu$, with ϵ_μ the photon polarization vector and $e = \sqrt{4\pi\alpha}$, the dimensionless proton electric charge and $\alpha \sim 1/137$.

To account for direct and crossed nucleon pole contributions, we need to consider, in addition to the isovector part, the isoscalar part of the electromagnetic current. For the isoscalar part of the electromagnetic current we have from Eq. (A5)

$$\langle n\pi^+ | s_{\text{em } IS}^\mu | p \rangle = \langle p\pi^- | s_{\text{em } IS}^\mu | n \rangle = \sqrt{2} \langle p\pi^0 | s_{\text{em } IS}^\mu | p \rangle = -\sqrt{2} \langle n\pi^0 | s_{\text{em } IS}^\mu | n \rangle \quad (\text{A16})$$

Using the current of Eq. (A13), supplemented by including i) the q^2 dependence induced by the Dirac $F_1^{p,n}$ form factors and ii) the magnetic contribution in the γNN vertex (with the corresponding magnetic form factors $\mu_p F_2^p(q^2), \mu_n F_2^n(q^2)$, for which we also use the Galster parametrization), we find [1]

$$\langle p\pi^0 | s_{\text{em } IS}^\mu | p \rangle = -\frac{\langle n\pi^0 | s_{\text{em}}^\mu(0) | n \rangle - \langle p\pi^0 | s_{\text{em}}^\mu(0) | p \rangle}{2} \quad (\text{A17})$$

$$\begin{aligned} &= -i \frac{g_A}{2f_\pi} \bar{u}(\vec{p}') \left\{ \not{k}_\pi \gamma_5 \frac{\not{p} + \not{q} + M}{(p+q)^2 - M^2 + i\epsilon} \left[F_1^{IS}(q^2) \gamma^\mu + i\mu_{IS} \frac{F_2^{IS}(q^2)}{2M} \sigma^{\mu\nu} q_\nu \right] \right. \\ &\quad \left. + \left[F_1^{IS}(q^2) \gamma^\mu + i\mu_{IS} \frac{F_2^{IS}(q^2)}{2M} \sigma^{\mu\nu} q_\nu \right] \frac{\not{p}' - \not{q} + M}{(p'-q)^2 - M^2 + i\epsilon} \not{k}_\pi \gamma_5 \right\} u(\vec{p}) \end{aligned} \quad (\text{A18})$$

with

$$F_1^{IS}(q^2) = \frac{1}{2} (F_1^p(q^2) + F_1^n(q^2)), \quad \mu_{IS} F_2^{IS}(q^2) = \frac{1}{2} (\mu_p F_2^p(q^2) + \mu_n F_2^n(q^2)) \quad (\text{A19})$$

where we have made use of the cancellation of the isovector contributions in the difference $(\langle n\pi^0 | s_{\text{em}}^\mu(0) | n \rangle - \langle p\pi^0 | s_{\text{em}}^\mu(0) | p \rangle)$.

Taking also into account the isovector contributions, we get the following direct and crossed nucleon pole amplitudes:

$$\begin{aligned} j_{\text{em}}^\mu |_{\text{NP}} &= -i C_\gamma^{\text{NP}} \frac{g_A}{2f_\pi} \bar{u}(\vec{p}') \not{k}_\pi \gamma_5 \frac{\not{p} + \not{q} + M}{(p+q)^2 - M^2 + i\epsilon} V_{NP}^\mu(q) u(\vec{p}), \\ C_\gamma^{\text{NP}} &= \begin{pmatrix} 1 & \text{for } p \rightarrow p\pi^0 \\ \sqrt{2} & \text{for } p \rightarrow n\pi^+ \\ -1 & \text{for } n \rightarrow n\pi^0 \\ \sqrt{2} & \text{for } n \rightarrow p\pi^- \end{pmatrix}, \quad V_{\text{NP}}^\mu = \begin{pmatrix} V_p^\mu(q) & \text{for } p \rightarrow p\pi^0 \\ V_p^\mu(q) & \text{for } p \rightarrow n\pi^+ \\ V_n^\mu(q) & \text{for } n \rightarrow n\pi^0 \\ V_n^\mu(q) & \text{for } n \rightarrow p\pi^- \end{pmatrix} \end{aligned} \quad (\text{A20})$$

$$\begin{aligned} j_{\text{em}}^\mu |_{\text{CNP}} &= -i C_\gamma^{\text{CNP}} \frac{g_A}{2f_\pi} \bar{u}(\vec{p}') V_{CNP}^\mu(q) \frac{\not{p}' - \not{q} + M}{(p'-q)^2 - M^2 + i\epsilon} \not{k}_\pi \gamma_5 u(\vec{p}), \\ C_\gamma^{\text{CNP}} &= \begin{pmatrix} 1 & \text{for } p \rightarrow p\pi^0 \\ \sqrt{2} & \text{for } p \rightarrow n\pi^+ \\ -1 & \text{for } n \rightarrow n\pi^0 \\ \sqrt{2} & \text{for } n \rightarrow p\pi^- \end{pmatrix}, \quad V_{\text{CNP}}^\mu = \begin{pmatrix} V_p^\mu(q) & \text{for } p \rightarrow p\pi^0 \\ V_n^\mu(q) & \text{for } p \rightarrow n\pi^+ \\ V_n^\mu(q) & \text{for } n \rightarrow n\pi^0 \\ V_p^\mu(q) & \text{for } n \rightarrow p\pi^- \end{pmatrix} \end{aligned} \quad (\text{A21})$$

with

$$V_{p,n}^\mu(q) = F_1^{p,n}(q^2) \gamma^\mu + i\mu_{p,n} \frac{F_2^{p,n}(q^2)}{2M} \sigma^{\mu\nu} q_\nu \quad (\text{A22})$$

One can check that CVC is preserved by the non-resonant amplitudes.

Finally, we give the expressions for de DP and CDP $N^*(1520)$ terms. The isovector parts are determined, as for the case of the Δ , in terms of the matrix elements of the V_{cc+}^μ weak vector current that appear in the appendix of Ref. [10]. They are given by

$$\begin{aligned} j_{\text{em IV}}^\mu |_{\text{DP}} &= i C_{\text{IV}}^{\text{DP}} g_D \frac{1}{2\sqrt{3}} \frac{k_\pi^\alpha}{p_D^2 - M_D^2 + iM_D \Gamma_D} \bar{u}(\vec{p}') \gamma_5 P_{\alpha\beta}^D(p_D) \Gamma_D^{V\beta\mu}(p, q) u(\vec{p}), \\ p_D &= p + q, \quad C_{\text{IV}}^{\text{DP}} = \begin{pmatrix} 1 & \text{for } p \rightarrow p\pi^0 \\ \sqrt{2} & \text{for } p \rightarrow n\pi^+ \\ 1 & \text{for } n \rightarrow n\pi^0 \\ -\sqrt{2} & \text{for } p \rightarrow p\pi^- \end{pmatrix} \end{aligned} \quad (\text{A23})$$

$$j_{\text{em IV}}^\mu|_{\text{CDP}} = -iC_{\text{IV}}^{\text{CDP}} g_D \frac{1}{2\sqrt{3}} \frac{k_\pi^\alpha}{p_D^2 - M_D^2 + iM_D\Gamma_D} \bar{u}(\vec{p}') \hat{\Gamma}_V^{D\mu\beta}(p', -q) P_{\beta\alpha}^D(p_D) \gamma_5 u(\vec{p}),$$

$$p_D = p' - q, \quad C_{\text{IV}}^{\text{CDP}} = \begin{pmatrix} 1 & \text{for } p \rightarrow p\pi^0 \\ -\sqrt{2} & \text{for } p \rightarrow n\pi^+ \\ 1 & \text{for } n \rightarrow n\pi^0 \\ \sqrt{2} & \text{for } p \rightarrow p\pi^- \end{pmatrix}, \quad \hat{\Gamma}_V^{D\mu\beta}(p', -q) = \gamma^0 [\Gamma_V^{D\beta\mu}(p', -q)]^\dagger \gamma^0. \quad (\text{A24})$$

with $M_D = 1520$ MeV, and

$$P_{\alpha\beta}^D(p_D) = -(\not{p}_D + M_D) \left(g_{\alpha\beta} - \frac{1}{3} \gamma_\alpha \gamma_\beta - \frac{2}{3} \frac{p_{D\alpha} p_{D\beta}}{M_D^2} + \frac{1}{3} \frac{p_{D\alpha} \gamma_\beta - p_{D\beta} \gamma_\alpha}{M_D} \right) \quad (\text{A25})$$

$$\Gamma_V^{D\beta\mu}(p, q) = \left[\frac{\tilde{C}_3^V}{M} (g^{\beta\mu} \not{q} - q^\beta \gamma^\mu) + \frac{\tilde{C}_4^V}{M^2} (g^{\beta\mu} q \cdot p_D - q^\beta p_D^\mu) + \frac{\tilde{C}_5^V}{M^2} (g^{\beta\mu} q \cdot p - q^\beta p^\mu) + \tilde{C}_6^V g^{\beta\mu} \right], \quad p_D = p + q. \quad (\text{A26})$$

The corresponding vector form factors are given in Ref. [10] and they are obtained from a fit to results in Ref. [11].

The value of the g_D strong coupling is determined from the $\Gamma_{D_{13} \rightarrow N\pi}(M_D)$ partial decay width to be $g_D = 20 \text{ GeV}^{-1}$. This partial decay width is given, for $W_{\pi N} > M + m_\pi$, by

$$\Gamma_{D_{13} \rightarrow N\pi}(W_{\pi N}) = \frac{g_D^2}{8\pi} \frac{1}{3W_{\pi N}^2} [(W_{\pi N} - M)^2 - m_\pi^2] |\vec{p}_\pi|^3 \quad (\text{A27})$$

with $|\vec{p}_\pi| = \frac{\lambda^{1/2}(W_{\pi N}^2, M^2, m_\pi^2)}{2W_{\pi N}}$. For $\Gamma_{D_{13} \rightarrow N\pi}(M_D)$ we took 61% of 115 MeV. For the total width Γ_D we use

$$\Gamma_D(W_{\pi N}) = \Gamma_{D_{13} \rightarrow N\pi}(W_{\pi N}) + \Gamma_{D_{13} \rightarrow \Delta\pi}(W_{\pi N}). \quad (\text{A28})$$

where for $\Gamma_{D_{13} \rightarrow \Delta\pi}$ we assumed an S -wave decay and took

$$\Gamma_{D_{13} \rightarrow \Delta\pi}(W_{\pi N}) = 0.39 \times 115 \text{ MeV} \frac{|\vec{p}_\pi'|}{|\vec{p}_\pi'^2 - s|} \theta(W_{\pi N} - M_\Delta - m_\pi), \quad (\text{A29})$$

with $|\vec{p}_\pi'| = \frac{\lambda^{1/2}(W_{\pi N}^2, M_\Delta^2, m_\pi^2)}{2W_{\pi N}}$ and $|\vec{p}_\pi'^2 - s| = \frac{\lambda^{1/2}(M_D^2, M_\Delta^2, m_\pi^2)}{2M_D}$.

As for the matrix elements of the isoscalar part of the electromagnetic current associated to the $N^*(1520)$, we make use of the relations given in Eq. (A16) and the expression for $\langle n\pi^0 | s_{\text{em, IS}}^\mu(0) | n \rangle$ given in Ref. [10]. Finally,

$$j_{\text{em IS}}^\mu|_{DP} = iC_{\text{IS}}^{DP} g_D \frac{1}{\sqrt{3}} \frac{k_\pi^\alpha}{p_D^2 - M_D^2 + iM_D\Gamma_D} \bar{u}(\vec{p}') \gamma_5 P_{\beta\alpha}^D(p_D) \Gamma_V^{D\beta\mu}(p, q) u(\vec{p}),$$

$$p_D = p + q, \quad C_{\text{IS}}^{DP} = \begin{pmatrix} 1 & \text{for } p \rightarrow p\pi^0 \\ \sqrt{2} & \text{for } p \rightarrow n\pi^+ \\ -1 & \text{for } n \rightarrow n\pi^0 \\ \sqrt{2} & \text{for } p \rightarrow p\pi^- \end{pmatrix}, \quad (\text{A30})$$

$$j_{\text{em IS}}^\mu|_{CDP} = -iC_{\text{IS}}^{CDP} g_D \frac{1}{\sqrt{3}} \frac{k_\pi^\alpha}{p_D^2 - M_D^2 + iM_D\Gamma_D} \bar{u}(\vec{p}') \hat{\Gamma}_V^{D\mu\beta}(p', -q) P_{\beta\alpha}(p_D) \gamma_5 u(\vec{p}),$$

$$p_D = p' - q, \quad C_{\text{IS}}^{CDP} = \begin{pmatrix} 1 & \text{for } p \rightarrow p\pi^0 \\ \sqrt{2} & \text{for } p \rightarrow n\pi^+ \\ -1 & \text{for } n \rightarrow n\pi^0 \\ \sqrt{2} & \text{for } p \rightarrow p\pi^- \end{pmatrix}, \quad \hat{\Gamma}_V^{D\mu\beta}(p', -q) = \gamma^0 [\Gamma_V^{D\beta\mu}(p', -q)]^\dagger \gamma^0. \quad (\text{A31})$$

with

$$\Gamma_V^{D\beta\mu} = \left[\frac{\tilde{C}_3^{V, \text{IS}}}{M} (g^{\beta\mu} \not{q} - q^\beta \gamma^\mu) + \frac{\tilde{C}_4^{V, \text{IS}}}{M^2} (g^{\beta\mu} q \cdot p_D - q^\beta p_D^\mu) + \frac{\tilde{C}_5^{V, \text{IS}}}{M^2} (g^{\beta\mu} q \cdot p - q^\beta p^\mu) + \tilde{C}_6^{V, \text{IS}} g^{\beta\mu} \right] \quad (\text{A32})$$

The isoscalar form factors are given in Ref. [10]. For them we use the same functional form as for the \tilde{C}_j^V while their values at $q^2 = 0$ have been taken from Ref. [12].

Finally, the differential $\gamma N \rightarrow N' \pi$ cross section in the laboratory (LAB) frame for real photons is obtained from the amplitudes j_{em}^μ as

$$\left. \frac{d^2\sigma}{d\cos(\theta_\pi)dE_\pi} \right|_{\text{LAB}} = -\frac{\alpha|\vec{k}_\pi|}{16M|\vec{q}|E'} \left(\sum_{\text{spins}} j_{\text{em}}^\mu j_{\mu\text{em}}^* \right) \delta(q^0 + M - E_\pi - E') \quad (\text{A33})$$

The energy conservation Dirac delta fixes the pion polar angle in the LAB frame as

$$\cos(\theta_\pi) = \frac{2M(E_\pi - q^0) + 2q^0 E_\pi - m_\pi^2}{2q^0 |\vec{k}_\pi|} \quad (\text{A34})$$

Finally, the average and sum over the initial and final nucleon spins in Eq. (A33) is readily done thanks to

$$\sum_{\text{spins}} \bar{u}(\vec{p}') \mathcal{S}^\mu u(\vec{p}) [\bar{u}(\vec{p}') \mathcal{S}_\mu u(\vec{p})]^* = \frac{1}{2} \text{Tr}((\not{p}' + M) \mathcal{S}^\mu (\not{p} + M) \gamma^0 \mathcal{S}_\mu^\dagger \gamma^0) \quad (\text{A35})$$

where the spin dependence of the Dirac's spinors is understood and \mathcal{S}^μ is a matrix in the Dirac's space for each value of the Lorentz index μ .
